Here are notes I took while watching your presentation:

- It's great that you based your code on the existing graph implementation we studied in this class
- I wonder if the bond type should be defined as enums...
- `element_terminology()` should probably use set/dict instead of list to speed up retrieval
- As mentioned in some assignment commentary, it's not a good idea to compare str's, which can change without changing the actual data. Compare individual attributes, perhaps?
- I see where you are going with this. Interesting ways to represent Atoms, Bonds, and Molecules with graph!
- SMILE seems really cool, not the least because it uses so many graph algorithms!
- When explaining the SMILE parser, you should walk through an example of how DFS is used before diving into the code.
- It would be nice to explain and walk through an example of Floyd-Marshall, though that could be a project in itself.
- Wow, you went through the boiling points of lots of molecules!

Vishagan, that's an awesome project you did! This seems like a very good application of graph. For a topic of such complexity, you explained the concepts, applications, and code clearly. Your implementation and tests were also very well written. Overall it's amazing and, even though much of the chemistry is over my head, I've learned a lot! Thank you for the hard work and sharing it!
